CredShields

Smart Contract Audit

April 20, 2026 • CONFIDENTIAL

Description

This document details the process and result of the Smart Contract audit performed by CredShields Technologies PTE. LTD. on behalf of Hearth between March 3, 2026, and March 9, 2026. A retest was performed on April 20, 2026.

1. Executive Summary ----------

Hearth engaged CredShields to perform a smart contract audit from March 3, 2026, to March 9, 2026. During this timeframe, 12 vulnerabilities were identified. **A retest was performed on April 20, 2026, and all the bugs have been addressed.**

During the audit, 0 vulnerabilities were found with a severity rating of either High or Critical. These vulnerabilities represent the greatest immediate risk to "Hearth" and should be prioritized for remediation, and fortunately, none were found.

The table below shows the in-scope assets and a breakdown of findings by severity per asset. Section 2.3 contains more information on how severity is calculated.

Assets in Scope	Critical	High	Medium	Low	info	Gas	Σ
T-Rex Contracts	0	0	0	6	6	0	**12**

Table: Vulnerabilities Per Asset in Scope

The CredShields team conducted the security audit to focus on identifying vulnerabilities in T-Rex Contract's scope during the testing window while abiding by the policies set forth by Hearth's team.

State of Security

To maintain a robust security posture, it is essential to continuously review and improve upon current security processes. Utilizing CredShields' continuous audit feature allows both Hearth's internal security and development teams to not only identify specific vulnerabilities but also gain a deeper understanding of the current security threat landscape.

To ensure that vulnerabilities are not introduced when new features are added, or code is refactored, we recommend conducting regular security assessments. Additionally, by analyzing the root cause of resolved vulnerabilities, the internal teams at Hearth can implement both manual and automated procedures to eliminate entire classes of vulnerabilities in the future. By taking a proactive approach, Hearth can future-proof its security posture and protect its assets.

2. The Methodology ----------

Hearth engaged CredShields to perform a T-Rex Contract's audit. The following sections cover how the engagement was put together and executed.

2.1 Preparation Phase

The CredShields team meticulously reviewed all provided documents and comments in the smart contract code to gain a thorough understanding of the contract's features and functionalities. They meticulously examined all functions and created a mind map to systematically identify potential security vulnerabilities, prioritizing those that were more critical and business-sensitive for the refactored code. To confirm their findings, the team deployed a self-hosted version of the smart contract and performed verifications and validations during the audit phase.

A testing window from March 3, 2026, to March 9, 2026, was agreed upon during the preparation phase.

2.1.1 Scope

During the preparation phase, the following scope for the engagement was agreed upon:

IN SCOPE ASSETS
TrustedIssuersRegistry: https://testnet.bscscan.com/address/0xda79eCBEdA111cc1C47ba99564F0966e6dbF4F38 **ClaimTopicsRegistry:** https://testnet.bscscan.com/address/0x73D9B0C921FFE7dBB2ac5A77d672770b5F8789E0 **IdentityRegistryStorage:** https://testnet.bscscan.com/address/0xc8cabB5399B00cEe602b55720Fe8A54881168b71 **IdentityRegistry:** https://testnet.bscscan.com/address/0x73793774FD18bdfA105a90A1a6191315ed76486c

2.1.2 Documentation

Documentation was not required as the code was self-sufficient for understanding the project.

2.1.3 Audit Goals

CredShields employs a combination of in-house tools and thorough manual review processes to deliver comprehensive smart contract security audits. The majority of the audit involves manual inspection of the contract's source code, guided by OWASP's Smart Contract Security Weakness Enumeration (SCWE) framework and an extended, self-developed checklist built from industry best practices. The team focuses on deeply understanding the contract's core logic, designing targeted test cases, and assessing business logic for potential vulnerabilities across OWASP's identified weakness classes.

CredShields aligns its auditing methodology with the OWASP Smart Contract Security projects, including the Smart Contract Security Verification Standard (SCSVS), the Smart Contract Weakness Enumeration (SCWE), and the Smart Contract Secure Testing Guide (SCSTG). These frameworks, actively contributed to and co-developed by the CredShields team, aim to bring consistency, clarity, and depth to smart contract security assessments. By adhering to these OWASP standards, we ensure that each audit is performed against a transparent, community-driven, and technically robust baseline. This approach enables us to deliver structured, high-quality audits that address both common and complex smart contract vulnerabilities systematically.

2.2 Retesting Phase

Hearth is actively partnering with CredShields to validate the remediations implemented towards the discovered vulnerabilities.

2.3 Vulnerability classification and severity

CredShields follows OWASP's Risk Rating Methodology to determine the risk associated with discovered vulnerabilities. This approach considers two factors - Likelihood and Impact - which are evaluated with three possible values - **Low**, **Medium**, and **High**, based on factors such as Threat agents, Vulnerability factors, and Technical and Business Impacts. The overall severity of the risk is calculated by combining the likelihood and impact estimates.

Overall Risk Severity				
Impact	HIGH	Medium	High	Critical
	MEDIUM	Low	Medium	High
	LOW	None	Low	Medium
		LOW	MEDIUM	HIGH
Likelihood				

Overall, the categories can be defined as described below -

1. **Informational**

   We prioritize technical excellence and pay attention to detail in our coding practices. Our guidelines, standards, and best practices help ensure software stability and reliability. Informational vulnerabilities are opportunities for improvement and do not pose a direct risk to the contract. Code maintainers should use their own judgment on whether to address them.

2. **Low**

Low-risk vulnerabilities are those that either have a small impact or can't be exploited repeatedly or those the client considers insignificant based on their specific business circumstances.

3. **Medium**

   Medium-severity vulnerabilities are those caused by weak or flawed logic in the code and can lead to exfiltration or modification of private user information. These vulnerabilities can harm the client's reputation under certain conditions and should be fixed within a specified timeframe.

4. **High**

   High-severity vulnerabilities pose a significant risk to the Smart Contract and the organization. They can result in the loss of funds for some users, may or may not require specific conditions, and are more complex to exploit. These vulnerabilities can harm the client's reputation and should be fixed immediately.

5. **Critical**

   Critical issues are directly exploitable bugs or security vulnerabilities that do not require specific conditions. They often result in the loss of funds and Ether from Smart Contracts or users and put sensitive user information at risk of compromise or modification. The client's reputation and financial stability will be severely impacted if these issues are not addressed immediately.

6. **Gas**

   To address the risk and volatility of smart contracts and the use of gas as a method of payment, CredShields has introduced a "Gas" severity category. This category deals with optimizing code and refactoring to conserve gas.

2.4 CredShields staff

The following individual at CredShields managed this engagement and produced this report:

- Shashank, Co-founder CredShields shashank@CredShields.com

Please feel free to contact this individual with any questions or concerns you have about the engagement or this document.

3. Findings Summary ----------

This chapter contains the results of the security assessment. Findings are sorted by their severity and grouped by asset and OWASP SCWE classification. Each asset section includes a summary highlighting the key risks and observations. The table in the executive summary presents the total number of identified security vulnerabilities per asset, categorized by risk severity based on the OWASP Smart Contract Security Weakness Enumeration framework.

3.1 Findings Overview

3.1.1 Vulnerability Summary

During the security assessment, 12 security vulnerabilities were identified in the asset.

Vulnerability Title	Severity	Vulnerability Type	Status
State Desynchronization Between Identity Registry Array and Agent Role	Low	Business Logic (SC03-LogicErrors)	Fixed
Uninitialized Implementation Contracts in Upgradeable Pattern	Low	Business Logic (SC03-LogicErrors)	Fixed

Table: Findings and Remediations

5. Bug Reports ----------

Bug ID #L01 [Fixed]

State Desynchronization Between Identity Registry Array and Agent Role

Vulnerability Type
Business Logic (SC03-LogicErrors)

Severity
Low

Description
The contract maintains bound Identity Registries using two separate mechanisms: the _identityRegistries array and the Agent role managed by AgentRoleUpgradeable. The bindIdentityRegistry function adds the registry to the array and grants the Agent role, while unbindIdentityRegistry removes the registry from the array and revokes the Agent role.

However, addAgent and removeAgent are public onlyOwner functions and can be called independently of the bind/unbind logic. This can cause state desynchronization.

For example, if the owner directly calls removeAgent on a bound registry, the address remains in the _identityRegistries array but loses the Agent role. A later call to unbindIdentityRegistry will revert because removeAgent requires the account to already have the role.

Additionally, the contract does not check for duplicate entries when binding registries. If the role is manually removed and the registry is bound again, duplicate entries can appear in _identityRegistries. The unbindIdentityRegistry function also emits an unbound event even if the address was not present in the array.

Affected Code

- 0xc8cabB5399B00cEe602b55720Fe8A54881168b71#code#F1#L133
- 0xc8cabB5399B00cEe602b55720Fe8A54881168b71#code#F1#L144

Impacts
Array entries can become inconsistent with the Agent role mapping, potentially leaving stale or duplicate entries and causing unbindIdentityRegistry to revert.

Remediation

Ensure synchronization between the array and role mapping by preventing direct use of addAgent and removeAgent, checking for duplicate entries during binding, and verifying that the registry exists in the array before executing role removal during unbinding.

Retest

This issue has been fixed.

Bug ID #L02 [Fixed]

Uninitialized Implementation Contracts in Upgradeable Pattern

Vulnerability Type
Business Logic (SC03-LogicErrors)

Severity
Low

Description
The implementation contracts use OpenZeppelin's Initializable upgradeable pattern but do not disable initializers in the constructor. As a result, the implementation contracts themselves can be initialized directly by any external account.

An attacker could call the init() function on the implementation contract and become its owner. Although this does not affect proxy instances because proxies use their own storage, leaving implementation contracts initializable is against OpenZeppelin upgradeable contract best practices and can create confusion when interacting with the implementation address.

Affected Code

- 0x73D9B0C921FFE7dBB2ac5A77d672770b5F8789E0#code#F1#L71

Impacts
An attacker can initialize the implementation contract and obtain ownership of it, which may lead to misleading state or confusion for users interacting with the implementation address.

Remediation
Add a constructor to each implementation contract that disables initializers.

Retest
This issue has been fixed by implementing disables in the initializer.

Bug ID #L03 [Fixed]

Missing Storage Gap in Upgradeable Base Contract

Vulnerability Type
Missing functionality (SCWE-006)

Severity
Low

Description
The AgentRoleUpgradeable contract is used as a base contract in an upgradeable proxy architecture and declares the state variable Roles.Role private _agents. However, the contract does not include a storage gap at the end of the contract. In upgradeable contract patterns, storage gaps are commonly reserved to allow safe addition of new state variables in future upgrades without affecting the storage layout of inherited contracts.

Because child contracts such as IdentityRegistryStorage and IdentityRegistry inherit from AgentRoleUpgradeable, their storage variables are placed immediately after _agents. If new state variables are added to AgentRoleUpgradeable in a future upgrade, the storage layout may shift and overlap with storage slots used by child contracts, potentially corrupting contract state.

Affected Code

- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F15#L70

Impacts
Future upgrades that introduce new state variables in AgentRoleUpgradeable may change the storage layout and overwrite storage used by child contracts, leading to state corruption.

Remediation
Add a storage gap at the end of the contract to reserve storage space for future variables.

Retest
This issue has been fixed by adding a storage gap in the contract.

Bug ID #L04 [Fixed]

Missing Zero Address Validation in Setter Functions

Vulnerability Type
Lack of Input Validation (SC04-Lack Of Input Validation)

Severity
Low

Description
The IdentityRegistry contract validates that all registry addresses are non-zero during initialization in the init() function. However, the setter functions setIdentityRegistryStorage, setClaimTopicsRegistry, and setTrustedIssuersRegistry do not perform the same validation. This allows the owner to set these critical registry addresses to address(0) by mistake. Since these addresses are used by the verification logic and identity management functions, assigning a zero address can break the interaction with the required registry contracts.

Affected Code

- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F1#L148
- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F1#L156
- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F1#L164

Impacts
If any of these registry addresses are set to address(0), contract functions that depend on them may revert, temporarily breaking identity verification and related operations until the correct address is set again.

Remediation
Add a zero address validation in each setter function to ensure that critical registry addresses cannot be set to address(0).

Retest
This issue has been fixed by adding a zero address validation.

Bug ID #L05 [Fixed]

Missing events in important functions

Vulnerability Type
Missing Best Practices

Severity
Low

Description
Events are inheritable members of contracts. When you call them, they cause the arguments to be stored in the transaction's log—a special data structure in the blockchain. These logs are associated with the address of the contract which can then be used by developers and auditors to keep track of the transactions.

The contract was found to be missing these events on certain critical functions which would make it difficult or impossible to track these transactions off-chain.

Affected Code

- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F16#L78
- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F16#L86

Impacts
Events are used to track the transactions off-chain and missing these events on critical functions makes it difficult to audit these logs if they're needed at a later stage.

Remediation
Consider emitting events for important functions to keep track of them.

Retest
This issue has been fixed.

Bug ID #L06 [Fixed]

Outdated Pragma

Vulnerability Type
Outdated Compiler Version (SCWE-061)

Severity
Low

Description
The smart contract is using an outdated version of the Solidity compiler specified by the pragma directive i.e. 0.8.17. Solidity is actively developed, and new versions frequently include important security patches, bug fixes, and performance improvements. Using an outdated version exposes the contract to known vulnerabilities that have been addressed in later releases. Additionally, newer versions of Solidity often introduce new language features and optimizations that improve the overall security and efficiency of smart contracts.

Affected Code

- 0xda79eCBEdA111cc1C47ba99564F0966e6dbF4F38#code#F1#L64
- 0x73D9B0C921FFE7dBB2ac5A77d672770b5F8789E0#code#F1#L63
- 0xc8cabB5399B00cEe602b55720Fe8A54881168b71#code#F1#L63
- 0xc8cabB5399B00cEe602b55720Fe8A54881168b71#code#F1#L63

Impacts
The use of an outdated Solidity compiler version can have significant negative impacts. Security vulnerabilities that have been identified and patched in newer versions remain exploitable in the deployed contract.
Furthermore, missing out on performance improvements and new language features can result in inefficient code execution and higher gas costs.

Remediation
It is suggested to use the 0.8.33 pragma version.
Reference: https://scs.owasp.org/SCWE/SCSVS-CODE/SCWE-061/

Retest
This issue has been fixed by using the 0.8.28 version.

Bug ID #I01 [Fixed]

Implicit Access Control on Administrative Functions

Vulnerability Type
Access Control (SCWE-016)

Severity
Informational

Description
The functions bindIdentityRegistry(address) and unbindIdentityRegistry(address) do not explicitly include an access control modifier. Access restriction currently relies on internal calls to addAgent and removeAgent, which contain the onlyOwner modifier. When these functions are called internally, Solidity still evaluates msg.sender as the original external caller, causing unauthorized calls to revert.

Although this prevents non-owners from executing the functions, the access control is implicit and not clearly defined at the function level. This pattern can reduce code clarity and may introduce risks during future upgrades or refactoring if the role management logic changes.

Affected Code

- 0xc8cabB5399B00cEe602b55720Fe8A54881168b71#code#F1#L133
- 0xc8cabB5399B00cEe602b55720Fe8A54881168b71#code#F1#L144

Impacts
There is no direct exploitability because unauthorized calls revert through the role check. However, relying on implicit access control reduces code clarity and may introduce security risks if internal logic changes in future upgrades.

Remediation
Add the onlyOwner modifier directly to bindIdentityRegistry and unbindIdentityRegistry to make the access control explicit and improve code clarity.

Retest
This issue has been fixed.

Bug ID #I02 [Fixed]

Untrusted Issuer Address Used in Claim Validation

Vulnerability Type
Lack of Input Validation (SC04-Lack Of Input Validation)

Severity
Informational

Description
The isVerified() function retrieves claims from a user's identity contract using getClaim(). The returned issuer address is then directly used to call IClaimIssuer(issuer).isClaimValid(). The contract does not verify that this issuer matches the expected trusted issuer address obtained from the trusted issuers registry.

Since the identity contract controls the data returned by getClaim(), a malicious or incorrectly configured identity contract could return an arbitrary issuer address. If the referenced contract always returns true for isClaimValid(), the verification logic could rely on an issuer that is not explicitly validated against the trusted issuers list. The current design assumes that only legitimate identity contracts are registered by agents, which aligns with the protocol's trust model.

Affected Code

- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F1#L198

Impacts
The verification logic depends on the issuer address returned by the identity contract without explicitly checking that it belongs to the trusted issuers list. Although the system relies on trusted identity registration by agents, this design weakens defense-in-depth guarantees.

Remediation
Add a validation step ensuring that the issuer returned from getClaim() matches the expected trusted issuer before calling isClaimValid().

Retest
This issue has been fixed.

Bug ID #I03 [Fixed]

Missing Array Length Validation in Batch Identity Registration

Vulnerability Type
Lack of Input Validation (SC04-Lack Of Input Validation)

Severity
Informational

Description
The batchRegisterIdentity function iterates using _userAddresses.length but does not validate that _identities.length and _countries.length match the same length. The function directly indexes these arrays inside the loop. If arrays with mismatched lengths are provided, Solidity 0.8+ will revert due to out-of-bounds access. Although this prevents state corruption, the revert occurs later during execution and produces a generic panic error instead of a clear validation error.

Affected Code

- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F1#L109

Impacts
Submitting arrays with mismatched lengths causes a generic revert during execution, making debugging harder and wasting gas due to late validation failure.

Remediation
Add an explicit check to ensure all input arrays have equal length before entering the loop.

Retest
This issue has been fixed.

Bug ID #I04 [Fixed]

Duplicate Claim Topics Allowed for Trusted Issuers

Vulnerability Type
Lack of Input Validation (SC04-Lack Of Input Validation)

Severity
Informational

Description
The functions addTrustedIssuer and updateIssuerClaimTopics accept an array of claim topics but do not check for duplicate values within the _claimTopics input. If duplicate claim topics are provided, the same trusted issuer can be inserted multiple times into the _claimTopicsToTrustedIssuers mapping array. As a result, read operations that fetch trusted issuers for a claim topic may return duplicate entries.

Affected Code

- 0xda79eCBEdA111cc1C47ba99564F0966e6dbF4F38#code#F1#L81
- 0xda79eCBEdA111cc1C47ba99564F0966e6dbF4F38#code#F1#L131

Impacts
Duplicate issuer entries may be returned by getTrustedIssuersForClaimTopic, leading to redundant processing and unnecessary gas usage in verification logic that iterates over the returned array.

Remediation
Add validation to prevent duplicate claim topics in the _claimTopics input array before inserting them into storage.

Retest
This issue has been fixed.

Bug ID #I05 [Fixed]

Silent Completion When Removing Non-Existing Claim Topic

Vulnerability Type
Improper Error Handling

Severity
Informational

Description
The removeClaimTopic function searches the _claimTopics array and removes the topic if found. If the provided topic does not exist in the array, the function completes execution without reverting or emitting any event. This results in a silent no-operation where the transaction succeeds but no change occurs.

Affected Code

- 0x73D9B0C921FFE7dBB2ac5A77d672770b5F8789E0#code#F1#L91

Impacts
Transactions attempting to remove a non-existing claim topic succeed silently, which may confuse off-chain monitoring systems and waste gas for ineffective operations.

Remediation
Add a check to ensure the claim topic exists before attempting removal, or revert if the topic is not found.

Retest
This issue has been fixed.

Bug ID #I06 [Fixed]

Roles.has( ) Reverts for Zero Address

Vulnerability Type
Lack of Input Validation (SC04-Lack Of Input Validation)

Severity
Informational

Description
The Roles library function has( ) checks whether an address possesses a role but includes a require statement that reverts if the provided account is the zero address. As a result, calling functions such as isAgent(address(0)) will revert instead of returning false. While the current codebase validates addresses before reaching this function, the behavior is unexpected for a view function that is typically used for safe role checks.

Affected Code

- 0x73793774FD18bdfA105a90A1a6191315ed76486c#code#F16#L95

Impacts
Future integrations or external contracts calling role-checking functions with address(0) may encounter unexpected reverts instead of receiving a simple false, which can cause unnecessary failures in composable contract interactions.

Remediation
Modify the function to safely return false when the provided address is the zero address instead of reverting.

Retest
This issue has been fixed.

6. The Disclosure ----------
